source("../R/get_qld.R")

set.seed(1)
```

This vignette explains how to use the `ppjsdm` package with the Queensland rainforest dataset from CSIRO. We begin by loading the data with the most prevalent species.

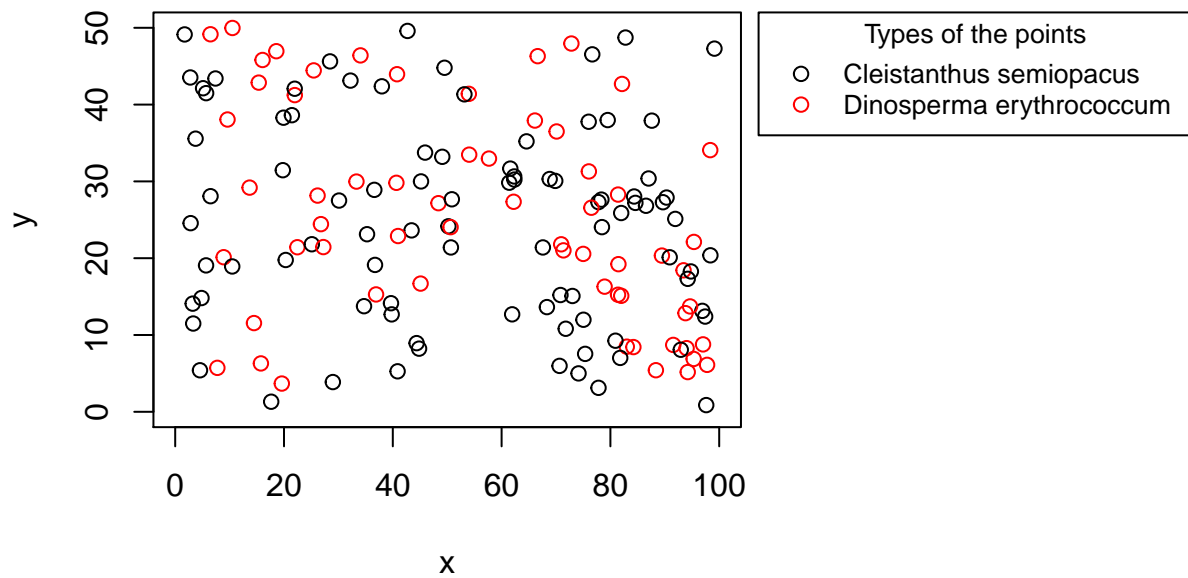

```
index_of_plot <- 3 # Between 1 and 20
year <- 2011 # Year of census
number_of_species <- 2 # Includes the most prevalent species from the plot

qld <- get_qld(index = index_of_plot,
               year = year,
               prevalent = number_of_species)
#> The chosen index corresponds to ep2.
configuration <- qld$configuration
window <- qld$window
```

The point configuration is plotted below.

```
par(mar = c(5, 4, 4, 13) + 0.1)
plot(configuration, window = window)
```

Points in the configuration

The function `gibbsm` fits a multivariate Gibbs point process to our dataset. For example,

```
fit <- ppjsdm::gibbsm(configuration, window = window, use_glmnet = TRUE)
#> 6 x 1 sparse Matrix of class "dgCMatrix"
#>
#> 1
#> (Intercept) .
#> log_lambda1 -4.0149275
#> log_lambda2 -4.4057282
#> alpha_1_1 .
#> alpha_1_2 0.4170228
#> alpha_2_2 .
plot(fit$complete)
```

By default, the function fits the model that was introduced in the ARC grant [TODO: Add reference]. This model has many drawbacks, the most important of which is that the model with the fitted values is degenerate, as can be seen by drawing from the model.

```

coefs <- fit$coefficients[-1]
lambda <- exp(coefs[1:2])
alpha <- matrix(c(coefs[3],
                  coefs[4],
                  coefs[4],
                  coefs[5]),
                ncol = number_of_species,
                nrow = number_of_species)
draw <- ppjsdm::rgibbs(window = window,
                      alpha = alpha,
                      lambda = lambda,
                      types = levels(types(configuration)),
                      steps = 1000000)

```

```

par(mar = c(5, 4, 4, 13) + 0.1)
plot(draw, window = window)

```

Points in the configuration

The Geyer model is better suited to most situations, but the user needs to specify some additional parameters before the fitting may take place.

```
radii <- matrix(5, number_of_species, number_of_species)
```

The matrix `radii` models interaction radii within a species, and between species. An interaction radius of 5 gives good results in the fitting procedure.

```
fit <- ppjsdm::gibbsm(configuration,
  window = window,
  model = "Geyer",
  radius = radii,
  use_glmnet = TRUE)
#> 6 x 1 sparse Matrix of class "dgCMatrix"
#>      1
#> (Intercept) .
#> log_lambda1 -4.2244880
#> log_lambda2 -4.7054733
#> alpha_1_1    0.1861782
#> alpha_1_2    .
#> alpha_2_2    0.3417358
plot(fit$complete)
```

Note that in this case the model is not degenerate; indeed we can sample from it as follows.

```

coefs <- fit$coefficients[-1]
lambda <- exp(coefs[1:2])
alpha <- matrix(c(coefs[3],
                  coefs[4],
                  coefs[4],
                  coefs[5]),
                ncol = number_of_species,
                nrow = number_of_species)
draw <- ppjsdm::rgibbs(window = window,
                      alpha = alpha,
                      lambda = lambda,
                      model = "Geyer",
                      radius = radii,
                      types = levels(types(configuration)))

par(mar = c(5, 4, 4, 13) + 0.1)
plot(draw, window = window)

```
